The information contained in ODARA 101 is most fully described in the *book*:

Evaluation of ODARA 101

[https://doi.org/10.1177%2F0886260514539762](https://doi.org/10.1177%2F0886260514539762)

Articles referred to in ODARA 101

While at the University of Regina, Dr. Kim Buchanan tested the ODARA’s prediction of criminal charges or convictions for domestic violence. In a two-year follow up of ninety-nine men convicted of a violent offence against their domestic partners, in the Canadian province of Saskatchewan, she reported a large predictive effect for the ODARA (AUC = .72).  
*(Learning Module 2: Validations of the ODARA, “Validations”)*

[https://doi.org/10.1177%2F0886260508317180](https://doi.org/10.1177%2F0886260508317180)

This article describes a case-control study, in which Danger Assessment scores were significantly higher among women interviewed after an attempted murder than women who were victims of less severe physical assault. *(Resources: “Domestic Murder”)*

In a study we conducted with Dr. Angela Eke of men who killed their female partners, their average score was in the highest ODARA category at the time of a previous domestic assault documented in police records. *(Learning Module 1: ODARA Research and Development, “Prediction”)*

This article provides an authorized translation of the ODARA in German.

In this study of 168 men who were arrested in Zurich for assaulting or seriously threatening their female partner, the ODARA risk category discriminated between general IPV recidivists and non-recidivists at a follow-up of three months with an AUC of .73. *(Learning Module 2: Validations of the ODARA, “Validations”)*

While at Carleton University in Ottawa, Andrew Gray tested the ODARA, DVRAG, and three other assessments among 94 federal offenders. The ODARA and DVRAG were the strongest predictors of intimate partner violence in a follow up of over 5 years, both with AUCs of .71. *(Learning Module 2: Validations of the ODARA, “More Recent Validation Studies for male offenders”)*

This manual explains how to score the PCL-R, which is an item in the Domestic Violence Risk Appraisal Guide (DVRAG). *(Resources: The ODARA/DVRAG System)*

Among 93 men with a police record against a female marital, cohabiting, or dating partner, the ODARA predicted post-index IPV with a moderate effect size (AUC = .67) in a 7.5 year follow up. The ODARA also predicted other offenses with a moderate or large effect size including stalking, sexual assault and non-violent offenses.

We have tested the ODARA’s predictive accuracy in several validation studies. In this study, we tested the predictive accuracy of the ODARA for men without an extensive criminal history.

The thirteen ODARA items were used to construct questions for an interview with the victim to ensure that the ODARA could also be used by professionals working in health care, shelters, victim services, or other services supporting victims of domestic violence. See this interview format in some of the videos in the scoring practice section of the ODARA 101 program.

Together with Dr. Suzanne Popham at the Algoma Treatment and Remand Centre in Ontario, we tested the ODARA’s predictive accuracy for criminal charges arising from domestic violence. The sample was limited to men incarcerated in a treatment centre, and the average ODARA score was in the second highest category. We followed these men up for an average of 8 years after release, and found that they spent about one third of that time in custody again. The ODARA significantly predicted recidivism in the full 8 year follow up and in follow-up periods as short as 6 months.

Men with lower ODARA scores were less likely to be arrested and convicted, even though the ODARA had not been invented at the time. In this study, arrest had no overall effect on domestic violence recidivism but a small beneficial effect in lower risk cases, mostly in terms of a delayed time until recidivism.

We have tested the ODARA’s predictive accuracy in several validation studies. In this study, we tested the predictive accuracy of the ODARA for men with an extensive criminal history; that is, a police record for wife assault and a correctional system file.

(Highlight Module 2: Validations of the ODARA, "Validations")

The ODARA was created from a study conducted by the Research Department in Penetanguishene, at the Waypoint Centre for Mental Health Care, in collaboration with the Ontario Provincial Police Behavioural Sciences and Analysis Services. This article describes the follow-up study, statistical analysis, and predictive accuracy in the original ODARA research and the first validation study.

(Highlight Module 1: ODARA Research and Development)

Fifty police officers scored the ODARA for two cases, either with or without the scoring instructions. The officers who had the instructions all scored the cases correctly. This article also describes the evaluation of the classroom training program on which ODARA 101 is based.

(Highlight Module 2: Validations of the ODARA, "Reliability: Do ODARA Users Agree?")

Together with Dr. Suzanne Popham at the Algoma Treatment and Remand Centre in Ontario, we tested the ODARA’s predictive accuracy for criminal charges arising from domestic violence. The sample was limited to women incarcerated in a treatment centre with a police record of violence against a current or former marital, common law, or dating partner; 6% of the partners were female. The average ODARA score was in the second highest category. We followed these women up for an average of nearly 9 years after release, and the ODARA score significantly predicted intimate partner violence recidivism. The overall rate of recidivism was 23%, and there was little evidence that items modified for offender gender predicted recidivism better than the unmodified ODARA.

(Highlight Module 2: Validations of the ODARA, “Validations”)

In a sample of 226 male perpetrators of actual or threatened violence, who were identified through police reports in Alberta and followed up for at least one year, the ODARA predicted subsequent convictions for any incident against an intimate partner with an AUC of .70. Any violent convictions were predicted with an AUC of .71, and charges (either violent or intimate-
partner related) produced AUCs of .67 and .66, respectively. The ODARA was scored with an inter-rater reliability of .91. (Learning Module 2: Validations of the ODARA, “Validations”) 

This article describes a prospective validation of the ODARA among 854 family violence offenders reported to police in Australia. The ODARA predicted intimate partner violent recidivism with a medium effect size, AUC = .68. It also predicted nonphysical intimate partner abuse with an AUC of .73. (Learning Module 2: Validations of the ODARA, “Validations”)

Angela Moser tested the ODARA’s prediction of new police reports for incidents of violence or other disputes against an intimate partner, among 174 male and 26 female perpetrators of such disputes, in the Canadian province of New Brunswick. The overall moderate predictive effect of the ODARA (AUC = .70), and AUC of .67 for female offenders. Prediction was improved by adding items measuring psychopathy. (Learning Module 2: Validations of the ODARA, “Validations”)

This study explores how the ODARA can be used to guide treatment intensity decisions for IPV offenders. It illustrates how low, medium, and high treatment intensity categories can be created, using data from the ODARA construction and validation research, and focusing on men with criminal charges for the index assault. It recommends that batterer intervention programs use this approach, in order to apply the principles of effective intervention and improve treatment outcomes. (Learning Module: Validations of the ODARA, “Validations”)

This study followed up 66 male domestic sexual assaulters for about 5 years after release from the Austrian Prison System. The domestic violence recidivism rate was 21% overall, and the ODARA predicted this recidivism with an AUC of .71. The ODARA also predicted criminal and
general violent recidivism. The DVRAG (an algorithm for combining the ODARA and the Hare (2003) Psychopathy Checklist-Revised (PCL-R)) also predicted recidivism but did not improve prediction over and above the ODARA.

(\textit{Learning Module 5: Interpretation of Risk, “User’s interpretation of Risk”})

This study examined the accuracy of forensic experts using unstructured clinical judgment (UCJ) compared to graduate students scoring the ODARA in identifying high-risk perpetrators of IPV. After a mean follow-up period of 8.0 years, the base rate of violent recidivism was 20.0% and students using the ODARA were significantly more accurate than clinical experts in assessing long-term violent recidivism (AUC = .78 vs. 0.35). Raters without extensive clinical training were able to differentiate those spouses who carried on assaulting their intimate partner from those who desisted from violent behavior.

(\textit{Learning Module 2: Validations of the ODARA, “Validations”})

Outside of Ontario, police Sergeant Greg Stewart and Professor Kris Henning the ODARA’s ability to predict subsequent domestic incidents in police occurrence reports among men in Portland, Oregon. Not all of these men had committed a violent domestic incident in the past, and the researchers had to pro-rate for items pertaining to the index assault and to the victim’s children. They followed up the men for two years, and the ODARA significantly predicted domestic violence recidivism.

(\textit{Learning Module 2: Validations of the ODARA, “Validations”})

Among 64 men with a police record of domestic violence and attending domestic violence treatment in Orange County, California, the Domestic Violence Risk Appraisal Guide (DVRAG, an algorithm for combining the ODARA and a measure of psychopathy) predicted domestic violence recidivism with a large effect size.

(\textit{Learning Module 2: Validations of the ODARA, “More Recent Validation Studies for male offenders”})

Jennifer Ulmer tested the ODARA’s predictive validity when scored by police officers, among 268 men with a history of domestic violence. The average ODARA score was over 7, and the ODARA showed a small predictive effect for violence against persons, AUC = .57. Ulmer attributed this
poor performance to problems with training and use of the scoring instructions, as well as time constraints and limited information gathering.

(learning module 2: validations of the odara, “validations”)

other work on domestic violence

This paper describes a study of police officers’ use of the ODARA in domestic cases with and without use of physical violence by men and women. Police were more likely to make arrests in cases with higher ODARA scores and more physical violence and injury. The researchers concluded that the ODARA can improve decision making on discretionary matters. However, different definitions of IPV, limited understanding of the complexities of domestic abuse, and a focus on a single incident rather than the broader case history, reduced compliance with risk assessment policies.

Among 728 women whose male partners were arrested for IPV, women’s perceptions of risk were split into high risk and low risk. Scores on a 10-item modification of the ODARA were also split into two categories of high risk (scores of 6 or higher) and low risk (5 or lower). Categories of perceived risk were positively related to the ODARA categories, with 67% agreement and a kappa statistic of .34. Women with relatively high risk ODARA scores expected low risk more often than the other way around.

This study of 57 women in shelters examined some psychometric properties of the ODARA. Scores on the ODARA and the Danger Assessment were positively correlated. The ODARA had acceptable internal and split-half validity. Perpetrators’ age, where the victim lived, and victim pregnancy accounted for only 1.5% of the variance found in the ODARA responses.

Among stalking offenders, 77% committed new offenses and 33% committed violent recidivism, within an average follow-up of nearly 9 years. Most violent recidivism was against an intimate
Predictors of violent recidivism were similar to those in other populations: younger age at first offense, criminal history, failure on conditional release, and substance abuse.

This chapter looks at domestic violence through the lens of threat assessment. It describes the ODARA and other domestic violence risk assessment tools, and outlines how the guiding principles of risk, need, and responsivity apply to domestic violence assessment and intervention. The chapter also discusses victim safety and situational risk factors.

This article examines whether access to firearms increases assault severity or whether it is the characteristic of a subgroup of offenders who are more likely to commit severe and repeated domestic assault. Although firearm access and weapon use were related to actuarial risk of domestic violence recidivism, neither predicted occurrence or severity of recidivism.

In 185 men identified from police reports of IPV who were followed up for 5 years, 32% reoffended with IPV and the ODARA had a small and significant predictive effect (AUC = .63).

This systematic review of tools identified the ODARA one of the two most studied domestic violence risk assessment tools. Inter-rater reliability for ODARA scores across studies ranged from .90–.94. AUCs ranged from .64 to .77. Methodological differences across studies made it challenging to summarize validation findings.

This study identified 151 adult female suspects in police reports, and defined IPV defined as abusive, threatening, harassing, or violent behaviour intended to coerce an intimate partner. In an average three-year follow-up, 46 women (30%) had a new police contact for a domestic incident, with or without arrest. Only 3 recidivists were known to have committed a physical assault and the remaining reoffenses included harassment and breach of conditions. Researchers scored the ODARA with excellent reliability (total score ICC = .98, item ICCs ranged from .72 to 1.00). The

This study tested the ODARA in a sample of 300 men in a northern region of Canada. In an average follow-up of nearly 5 years, 45% committed IPV recidivism and the ODARA predicted IPV recidivism with a small effect size in the total sample and in the sub-sample of 278 Indigenous men (both AUCs = .62). Additional violent and non-violent outcomes were also studied in a variety of follow-up periods.

This article reports on interviews with assaulted women about their concerns for their children and how these concerns affected the decision to leave the assailant. Fifty-five percent of the women's children had witnessed violence, and 90% had become involved in the physical or psychological abuse in some way, even after separation. Fifty-five percent of the women left because of the risks to their children.

This edited book covers four major themes: historical framework of legal response to wife assault; police attitudes and action; prosecution, mediation, and treatment within the court system; and victims as defendants and participants in the legal system. The authors of each chapter describe evaluation research and highlight their own work in each area.

This invited article shows the scoring and interpretation of the ODARA and DVRAG in a case described by Cook et al. in the same journal issue. The ODARA and DVRAG interpretations with respect to risk assessment concur with conclusions drawn by Cook et al. using the B-SAFER and the SAM but in the actuarial model risk management depends on apportioning existing resources according to policy-level decisions informed by risk and on individual-level assessment of criminogenic needs and responsibility.

This chapter reviews risk assessment tools for intimate partner violence, as well as risk factors and correlates. It also discusses the potential for assessing risk after change, assessing risk among female domestic offenders, and practice issues in risk assessment and policing.

This chapter looks at the criminal justice response to domestic violence and describes the risk-need-responsivity model of effective correctional service. It then describes the ODARA and other domestic violence risk assessment tools, and criminogenic treatment needs related to domestic violence, and shows how the RNR model can help the field advance, especially in the practice of threat assessment.

This study of men undergoing forensic assessment looked at adverse childhood experiences (ACEs) such as childhood abuse, witnessing domestic violence, and parental mental illness. The 99 men with a current or previous offense of intimate partner violence (IPV) had more ACEs than two other groups (233 men with violent offenses other than IPV and 103 men with nonviolent criminal histories). Among the men with IPV histories, higher ACEs were related to higher actuarial risk of violent recidivism. There was insufficient evidence to conclude that ACEs represent a criminogenic treatment need for men who committed IPV.

This article examines psychopathy, the Violence Risk Appraisal Guide (VRAG), and motives thought to be related to men’s violence against female domestic partners, among men with a history of serious domestic violence. Violent recidivism was lower among these men than among a larger sample of generally violent offenders.

We studied the step-father effect, whereby children are more risk of physical abuse by parents than are children genetically related to their parents, in domestically violent men who had a minor child at the time of their ODARA index assault. Men were more likely to assault their step-children, an effect observed at all levels of offender antisociality.

This non-technical review examines the research evidence for the prediction of domestic violence recidivism by men against their female partners, lethal domestic violence, and the onset of domestic violence. A glossary of terms is included. Data from the ODARA research regarding the effect of domestic violence treatment attendance are presented. Because of statistical and practical limitations to predicting lethal assault, we recommend using an actuarial assessment of assault risk, plus attention to the strongest correlates of lethal assault when lethality is a concern.

This chapter reviews the history and effectiveness of legislation, policing, prosecution, and alternative approaches to domestic violence. The more extensive knowledge about criminal justice responses to other forms of criminal conduct is described, along with lessons that could be applied to domestic violence.

This chapter reviews the development and validations of the ODARA in non-technical language.

This brief article describes how to use PCL-R Facet 4 instead of the total PCL-R score as the 14th item on the DVRAG. In the same construction sample as reported in Hilton, Harris, Rice,
Houghton, & Eke (2008), the modified DVRAG had moderate predictive accuracy with an AUC of .71, and in the cross-validation sample it had a large predictive effect with an AUC of .73.

This study extended the one reported by Hilton, Ham, & Green (2019). The 99 men who had committed IPV had more of the Central Eight criminogenic treatment needs than the other men with violent or nonviolent criminal histories. The criminogenic needs that were highest in this group included: antisocial personality traits, procriminal attitudes, criminal associates, substance use, and poor marital and family relationships. This study supports targeting criminogenic treatment needs in domestic violence treatment programs.

This study reanalyzed data from the original ODARA construction and cross-validation data, looking at how criminogenic treatment needs were related to the ODARA and to domestic violence recidivism. Out of the seven needs measured, antisocial personality traits had the strongest association with recidivism and added positively and incrementally to the prediction of recidivism after the ODARA. This study supports targeting criminogenic treatment needs in domestic violence treatment programs.

This study is the first article from the Optimizing Risk Assessment for Domestic Violence (ORADV) project that evaluates risk and outcomes among men referred to a specialized threat assessment service following a police report of intimate partner violence. The sample scored higher on the ODARA than previously reported routine policing samples. Inter-rater reliability on the ODARA was $r = .84$. Percentage agreement on ODARA items ranged from 69% (victim concern) to 97% (victim’s biological child with a previous partner).

This chapter describes the research creating and validating the ODARA, the DVRAG, and other actuarial tools for violence risk assessment. Case scoring samples are included.

This study tests the validity of a new IPV risk assessment tool, the SAFVR, in New Zealand. The authors report that vAUCs for the SAFVR were smaller than previously found for the ODARA in New Zealand, reported in unpublished studies.

This study is the first in Canada to examine the predictive accuracy of the ODARA when scored by the investigating police officer. In 97 men who assaulted their female partner, the ODARA predicted general recidivism with medium to large effects (AUCs = .698 to .713), predicted violent recidivism with medium effects (AUCs = .629 to .700), and predicted IPV recidivism with small to medium effects (AUCs = .629 to .682). When predicting IPV recidivism, AUCs were statistically significant for reconvictions but not for police charges.

This study examined whether 226 police-reported cases of IPV had a history of stalking, and whether stalking improved prediction of IPV over and above risk assessment tools. Stalkers did not have significantly different ODARA scores or different IPV recidivism rates. In regression analyses, the ODARA significantly predicted IPV recidivism (and general recidivism). The ODARA remained significant when adding stalking to the model, and stalking did not improve prediction.

This study found that total ODARA scores were not significantly different between three groups of IPV perpetrators: 1. those committing intimate partner homicide; 2. A group who committed non-fatal IPV and were matched to the homicide group on age and sex; 3. a random sample of IPV cases from police reports.

This study followed 209 men and 100 women identified as perpetrators of IPV in police reports. In a 1-year follow up, 34% of men reoffended and the ODARA predicted this outcome with a medium effect size (AUC = .64). Women reoffended at a lower rate (18%) and the ODARA was not a significant predictor (AUC = .52).

This review identified the ODARA as the most accurate IPV risk assessment tool on average. The predictive accuracy of the ODARA in their meta-analysis (AUC = .67) was equivalent to a moderate effect size and statistically larger than that of the four other tools studied.

This study followed 99 women through police reports for one year. Only 20 women had committed IPV at the index assault, and only 6% of the total sample committed a subsequent IPV offense. AUCs for violent and nonviolent outcomes ranged from .40 to .56 and the confidence intervals were wide, with the result that none of these effects were significant.

Olver and Jung tested the ODARA’s predictive validity when scored from police files by researchers with good inter-rater reliability (correlation = .90). Among 289 men and women with a history of domestic violence in opposite-sex relationships, the average ODARA score was 5.4. The ODARA showed a large predictive effect in an average three-year follow up, AUC = .72. ODARA scores also predicted violent and general recidivism with large effects. Psychosocial adjustment items from the Spousal Assault Risk Assessment provided incremental predictive validity over the ODARA for intimate partner violence.

This study illustrates how treatment providers can identify treatment intensity categories using ODARA score distributions. Treatment providers can the highest risk individuals at intake using their own percentiles, and prioritize them for the best available, most intensive treatment.

This study validated the ODARA in a racially diverse sample of men in the United States. Of the 356 men 35% committed IPV recidivism against a female partner in a fixed 2-year follow-up. Due to limited information, only 11 ODARA items could be scored. This version of the ODARA predicted IPV recidivism with a small effect size (AUC = .59) and other violent and non-violent outcomes. There was poor calibration with 2-year IPV recidivism rates drawn from the original ODARA research.

This chapter describes the family of violence risk assessments developed by the Penetanguishene researchers using similar techniques. A second edition of this book is in progress, with an updated chapter including the VRAG-R and the DVRAG-4.

In this study, 88 men attending a court-mandated domestic violence treatment program were followed for 15 months. The average ODARA score was 5.5, and ODARA scores were highly correlated with scores on the SARA Version 3 (SARA-V3) measured before and after treatment. The ODARA predicted general recidivism with a large effect (AUC = .72) and treatment dropout with a medium effect (AUC = .70). This study did not measure IPV recidivism, but general violence (against any victim); the ODARA had a small effect (AUC = .63, not significant). SARA-V3 scores changed from pre- to post-treatment, and the post-treatment SARA-V3 scores improved prediction of general and violent recidivism over the ODARA. The authors concluded that there is growing support for using the ODARA and SARA in tandem.

This study identified 186 men and 44 women from police reports of IPV. In a 5-year follow-up, 18% of the men committed domestic violence recidivism and 27% committed general recidivism, and the ODARA had small predictive effects for these outcomes (AUCs = .58 and .60). The
women reoffended at a lower rate (9% IPV and 16% general recidivism) and the ODARA predicted outcomes with similar effect sizes (AUCs = .61 and .60). However, statistical significance was observed only for the prediction of general recidivism among men.

This review reported that actuarial tools performed better than other tools for domestic violence risk assessment.
